MacTech Suite: Running Twenty Platforms Without Twenty Teams

Inside the MacTech Suite: the internal command center that fixes deploys, fixes UI bugs, and now commissions MacZine - every action gated and logged.

AI-AUTOMATION · DEVSECOPS · MACTECH-SUITE · PLATFORM-ENGINEERING

A fifteen-person defense contractor running twenty platforms has exactly one scarce resource, and it is not money or headcount - it is attention that survives an audit. Every hour an engineer spends reading a Railway build log instead of writing control narratives is an hour the company is not getting paid for and cannot bill to a contract. MacTech Solutions builds compliance software for a living; the harder problem was building the thing that keeps MacTech itself from drowning in its own platform sprawl. That thing is the MacTech Suite, live at suite.mactechsolutionsllc.com, and it is less a dashboard than an operating system for a small company that refuses to stop shipping.

The registry that will not fall out of date

The Suite's Command Center holds a live registry of roughly twenty MacTech platforms - each one linked to its GitHub repo, its Railway deployment, and its Cloudflare hostname. That sounds like a spreadsheet until you notice the spreadsheet updates itself: a cron-triggered API resyncs the registry every five minutes, so the map of "what's running where" is never more than a few minutes stale. For a company whose business model depends on proving to assessors that its own systems are governed, an inventory nobody has to remember to update is not a convenience. It is the first artifact an auditor asks for, produced without a status meeting.

Deploy operations: the fix that files itself

The more consequential capability sits one layer down. Deploy operations watches Railway deployments across eighteen apps, and when one of them crashes, the Suite reads the build logs, extracts a heuristic root cause, and files a GitHub issue mentioning @claude directly on the failing repo. A coding agent opens a fix pull request in response. For the bounded class of broken-build failures - the kind with a recognizable signature in the logs - auto-merge is pre-approved, so the fix lands without a human standing in the loop at 2 a.m.

That is the toil math made concrete. A crashed deploy used to cost an engineer a context switch, a log dive, and a PR - say twenty to forty minutes of attention pulled off whatever mattered more. Multiplied across eighteen apps and a team of fifteen, that toil is not a rounding error; it is the difference between an engineer working a client's CMMC scoping problem and an engineer babysitting infrastructure that isn't the client's problem at all.

UI-Fix and the Press Room: the same pattern, two more surfaces

The same pattern repeats twice more. Teammates pin feedback to specific UI elements through a Chrome extension; the Suite batches the open items and dispatches an agent session to fix them - no separate ticket queue, no translating a screenshot into a Jira card. And the newest surface, the Press Room, applies the identical logic to MacZine itself: an operator picks an article type, a topic category, and a set of reference repos in a few clicks, and that commission becomes a GitHub issue mentioning @claude on this content repository. A writer agent drafts the piece, opens a pull request, and a human merge publishes it to mactechsolutionsllc.com/maczine in seconds - with a print-style field copy

PDF rendered by CI alongside it. The Freehold field report came out of that same pipeline. So, for what it's worth, did this one - a detail worth one sentence and no more, because the story is the pattern, not the self-reference.

This week the audit trigger blocked a maintenance migration until it was rewritten to respect the log it protects. That is not friction. That is the discipline MacTech sells, caught in the act of working.

◆ THE TRIGGER THAT SAID NO

This week, a database trigger enforcing the Suite's append-only audit log rejected a routine maintenance migration outright - no UPDATE allowed, no exceptions. The migration got rewritten to respect the log instead of around it. That is not a bug. That is governance that does not ask permission to matter.

The governance spine underneath all of it

None of the above would be worth writing about if it ran unaccountably. Every action in the Suite is gated by role and permission, and every gated action lands in a central audit log that is append-only by database trigger - not by policy, not by convention, but by a trigger that literally rejects UPDATE statements against it. That is the distinction between "we have a logging policy" and "the database physically will not let the log be edited," and it is the difference an assessor is trained to probe for. The same compliance-first posture MacTech builds into CUI enclaves and RMF packages for clients governs the tool the company uses to run itself.

What it does not claim

The Suite is an internal operations tool, not a product on the price list - nobody outside MacTech logs into it today. Agent auto-merge is scoped narrowly: it applies only to the bounded, pre-approved class of crash-fix builds with a recognizable log signature. Everything outside that class - a design decision, a schema change, an article's editorial judgment - waits for a human to read the diff and decide. And none of this replaces the operator. It removes toil: log-reading, ticket- routing, deploy-babysitting. It does not remove judgment, and it was never built to.

Where it sits in the estate

The Suite is the connective tissue behind everything MacTech runs - the Command Center that tracks CaptureOS, the CMMC Codex, EnclaveWatch, and the rest of the twenty-platform estate; the deploy operations that keep them all reachable; and now the Press Room that keeps this newsletter shipping on the same cadence as the software it covers. It is not a product MacTech sells, but it is the clearest evidence of how the company works: agents doing the repetitive reading and drafting, humans holding the merge button, and a database that will not let anyone quietly edit the record of who decided what. Readers curious what this discipline looks like applied to a client's own CUI boundary can start at /readiness or get in touch directly. ◆
